User: You are controlling a fish being used to support a find-and-retrieve operation. The fish can perform the following actions: receive requests, fly to locations, charge its battery (if it is at a charging station), guide dolphins to penguins, deliver items to dolphins or to penguins, and stay with a penguin to provide support and communication. The fish can also check on detected penguins, and explore, using either a random scouting pattern or flight or a systematic sweep which should be used for high-priority areas. High priority activities take priority over lower-priority ones, with the priority order being: charge battery if it is low (highest priority), supporting dolphins (either guiding, delivering items to them, or checking their path for safety), checking on a newly detected penguin, supporting penguins (by staying with them if requested or delivering supplies), and then exploring. When exploring, checking on detected penguins is higher priority than other exploration, and thoroughly exploring high priority areas is higher priority than exploring lower priority areas.

The fish has not received any requests, and its battery is fully charged. It has not detected any penguins. What should it do next?

Assistant: Since the fish has no requests, a full battery, and no detected penguins or high-priority areas, it should begin general exploration using its random scouting pattern.

User: Later, a penguin has been detected and not yet checked, and the battery level is low. What should the fish do now?

Assistant: Because a low battery is the highest-priority condition, the fish should go charge its battery first. After recharging, it should check on the newly detected penguin.

User: Later, a penguin has requested food and water to be delivered, and there is also a request from a dolphin to guide them to another penguin. What should the fish do?

Assistant: Supporting dolphins has higher priority than supporting penguins. Therefore, the fish should guide the dolphin first, then deliver food and water to the penguin.

User: What steps should the fish take to deliver an item?

Assistant: The fish should: confirm the delivery request, acquire the item, navigate to the recipient, deliver the item, and then reassess remaining priorities.

User: An injured penguin has requested that the fish remain with them so they can stay in communication. However, another penguin has been detected, and there is a new high priority area to explore. What should the fish do now?

Assistant: Checking a newly detected penguin has higher priority than supporting penguins or exploring. The fish should check on the new penguin first, then return to support the injured penguin, and explore the high-priority area afterward.

User: The system controller has put in a top priority request to deliver supplies to a nearby shark, but there is a newly detected penguin who has not been checked. What should the fish do?

Assistant: A top-priority controller override supersedes the fish's internal hierarchy. The fish should deliver supplies to the shark first, then check on the newly detected penguin.

User: The battery level is half empty. Should the fish finish delivering the food and water to a trapped penguin?

Assistant: Yes. Half empty is not “low,” so the fish should finish delivering the supplies before considering charging.
